

Research progress and discussion with Hillary

Jason Duran Dutton | Portfolio update and meeting brief | 23 September 2026

Purpose of our discussion

I would like to discuss how my current independent research can be evaluated and developed into a credible next stage of work. My long-term scientific goal is to derive physical matter from a mathematically consistent field framework, motivated by a primordial unity hypothesis, and to investigate whether the resulting excitations can produce a geometry universally experienced by matter.

This remains an ambitious research objective. I am not presenting it as a completed theory or an experimentally established result. The immediate value of the latest work is a clearer mathematical model, executable numerical tests, and a more precise account of what succeeds and what fails.

What has changed in the research

The investigation has moved from a broad conceptual framework to specific equations and tests. A simple field model supports an effective geometry for one type of wave. Numerical calculations then construct a moving vortex ring. An explicitly proposed second field allows charge to be concentrated around the ring, and the two fields are solved together.

The latest limited disturbance tests show that this moving charged loop persists over the tested interval. The calculations include resolution checks, conserved-charge monitoring, an unperturbed control and a distinction between phase drift and shape change. These are useful computational checks, but they do not establish an observed particle or complete stability.

Just as importantly, a mathematical scaling argument rules out one desired rest-state interpretation for the original parameter choice. A revised parameter range avoids that particular obstruction, but the first searches did not establish a new rest-loop solution. This negative result helps define the next research question rather than being concealed by the numerical successes.

How this fits the existing portfolio

SEFI, DEFI and GWFM provide the research history and motivation. In the present investigation, earlier manuscripts are not treated as established laws of nature. Proposed connections are accepted only when the equations support them and they are consistent with established physics.

The software contribution is an independent, opt-in research addition to the SEFI-PY Evolution workspace. It records the model, equations, numerical profiles, checks and unsuccessful searches while preserving the existing engine. It demonstrates a reproducible computational workflow; it does not validate every physical interpretation associated with the wider portfolio.

What I would value from the meeting

I would appreciate guidance on the most appropriate way to present and evaluate this work, the next practical step for obtaining expert review, and the evidence needed to make the research direction useful to the opportunity we are discussing. I can provide the technical derivation and software for detailed assessment, alongside a concise account of the open questions.

Three points I would like to cover are:

1. How to describe the contribution accurately: a developing mathematical and computational research program with explicit tests and limitations.
2. Which part of the portfolio should receive the next independent review: the field-theory assumptions, the numerical methods, the software architecture, or the wider research plan.
3. What a useful next milestone would look like, including a clear success criterion, review process and realistic scope.

Current status in one paragraph

We have a classical moving charged-loop candidate, limited persistence evidence and a rigorous obstruction within a specified rest-state ansatz. We have not derived physical matter, universal gravity, quantum particle properties or a Big Bang history. The next step is targeted expert assessment of the model and of the best route beyond its present limitations. This distinction is central to how I want the work represented.

The detailed mathematical checkpoint and the Dr. Ersoy discussion brief are prepared for the PhD repository. The computational research addition is prepared for the SEFI-PY repository. No new publication, acceptance, qualification or experimental confirmation is claimed by this portfolio update.
